Not illustrated. 1908 Excerpt: . be determined, from the same paper, and weigh it on the same balance. Then the area of the figure is equal to its weight divided by that of the square. The balance is one of the most important measuring instruments, and one of the most accurate. For this reason it is desirable to reduce, whenever possible, measurements of high accuracy to that of weight. The sensitiveness of a certain balance is defined as the angle through which it will turn when the difference between the weights in the pans is  $lmg$ . Thus, if  $s$  stands for sensitiveness,  $d$  for the angle of deflection when the difference in the weights is  $p$  mgr., then  $s = d/p$ . A more convenient form for computing the sensitiveness is derived as follows. Let (Fig. 8)  $l$  stand for the length of either arm of the balance,  $w$  the weight of the beam, with the center of gravity at  $G$ ,  $P$  and  $p$  the weights in the pan and their difference respectively, then, for a deflection  $\theta$ , when equilibrium is reached, we have  $(P + p)l \cos \theta = Pl \cos \theta + wd \sin \theta$ , where  $d$  is the distance of  $\theta$  from the fulcrum. From this it follows  $\tan \theta = pl/wd$ . We see from this that the sensitiveness is independent of the load  $P$  on the pans. However, if we consider the fact that the beam is not absolutely rigid, it can readily be followed that the...
