Not illustrated. 1822 Excerpt: . shew the angle at which the descending branch of the curve cuts the axis. 249. Coroll. 2. Beyond that point, the ordinate y becomes negative and increases indefinitely: not so the abscissa; r , which has a limit, that it does not pass; whence we may conclude that the descending branch of the curve has a vertical asymptote. For, when p is negative, we have $P = p t / (1 + ps) + \log. -p + V(+ pfi)$. therefore $P = -p V(+ p2) - \log. p + 1/(12)$. And if p , besides being negative, be very great, we may assume $1/(1 + p) = p$, and the logarithm may be neglected; because the logarithm is inconsiderable when compared with the number itself. When, therefore, p is negative and very great, $P = -p3$; and since the constant quantity C may also then be neglected, in comparison with p , we shall have--and $Ph--Ch hp Ph-Ch hp$ Whence $dx = ----$, and $Jk = econst. +----$; which value $hp hp$ does not increase indefinitely. But with respect to y , since $dy = -$, if--const. $+\log. p$; $hp h$ which value increases indefinitely along with p . 250. Proposition II. To construct the trajectory of a heavy projected obliquely in the air, when the angle of elevation is very small. The labour of constructing the curve by approximation becomes in this case more simple; for since the curve deviates very little from the axis, the abscissa x may be put for the arc s : whence $eh dx...$
